INVESTOR IN PEOPLE

The Patent Office  
Concept House  
Cardiff Road  
Newport  
South Wales  
NP10 8QQ

I, the undersigned, being an officer duly authorised in accordance with Section 74(1) and (4) of the Deregulation & Contracting Out Act 1994, to sign and issue certificates on behalf of the Comptroller-General, hereby certify that annexed hereto is a true copy of the documents as originally filed in connection with the patent application identified therein.

In accordance with the Patents (Companies Re-registration) Rules 1982, if a company named in this certificate and any accompanying documents has re-registered under the Companies Act 1980 with the same name as that with which it was registered immediately before re-registration save for the substitution as, or inclusion as, the last part of the name of the words "public limited company" or their equivalents in Welsh, references to the name of the company in this certificate and any accompanying documents shall be treated as references to the name with which it is so re-registered.

In accordance with the rules, the words "public limited company" may be replaced by p.l.c., plc, P.L.C. or PLC.

Re-registration under the Companies Act does not constitute a new legal entity but merely subjects the company to certain additional company law rules.

Signed

*Andrew Gensley*

**Warning**

*After an application for a patent has been filed, the Comptroller of the Patent Office will consider whether publication or communication of the invention should be prohibited or restricted under Section 22 of the Patents Act 1977. You will be informed if it is necessary to prohibit or restrict your invention in this way. Furthermore, if you live in the United Kingdom, Section 23 of the Patents Act 1977 stops you from applying for a patent abroad without first getting written permission from the Patent Office unless an application has been filed at least 6 weeks beforehand in the United Kingdom for a patent for the same invention and either no direction prohibiting publication or communication has been given, or any such direction has been revoked.*

**Notes**

- a) If you need help to fill in this form or you have any questions, please contact the Patent Office on 0645 500505.
- b) Write your answers in capital letters using black ink or you may type them.
- c) If there is not enough space for all the relevant details on any part of this form, please continue on a separate sheet of paper and write "see continuation sheet" in the relevant part(s). Any continuation sheet should be attached to this form.
- d) If you have answered 'Yes' Patents Form 7/77 will need to be filed.
- e) Once you have filled in the form you must remember to sign and date it.
- f) For details of the fee and ways to pay please contact the Patent Office.

## CRYSTAL STRUCTURE (II)

This application claims priority from UK application 0017376.5 filed July 14, 2000, the contents of which are incorporated herein by reference.

### 5 Field of the Invention

The present invention relates to the provision of a high resolution crystal structure of the prokaryotic 30S ribosome subunit, and the use of this structure in drug discovery.

### Background of the Invention

10 Translation of the genetic code occurs on the ribosome, a large nucleoprotein complex that consists of two subunits. In bacteria, the two subunits are denoted 30S and 50S. The 50S subunit contains the catalytic site of peptidyl transferase activity, while the 30S subunit plays a crucial role in decoding  
15 messenger RNA. Protein synthesis is a complex, multistep process that requires several extrinsic GTP-hydrolysing protein factors during each of the main stages of initiation, elongation and termination. Despite several decades of work, the molecular details of the process are poorly understood, and the  
20 elucidation of the mechanism of translation is one of the fundamental problems in molecular biology today. A recent collection of articles summarizes the state of understanding of the field.

25 An important contribution to this problem was made by Yonath and coworkers, who after nearly a decade of work showed that structures as large as the 50S ribosomal subunit would form crystals that diffract beyond 3 Å resolution (Ref 2). Originally, it was not clear that phase information from such a large asymmetric unit could be obtained to high resolution, but  
30 the development of bright, tunable synchrotron radiation sources, large and accurate area detectors, vastly improved crystallographic computing, and the advent of cryocrystallography have all contributed to making structural

studies of the ribosome more tractable. In our work, the use of anomalous scattering from the LIII edges of lanthanides and osmium has also played a critical role in obtaining phases (Ref 3).

5 The 30S ribosomal subunit (hereafter referred to as 30S) from *Thermus thermophilus* was originally crystallized by Trakhanov et al. in 2-methyl-2,4-pentanediol (MPD) (Ref 4) and soon afterwards by Yonath and coworkers in a mixture of ethyl-  
10 cbutanol and ethanol (Ref 5). Subsequent work by both groups showed that the MPD crystal form diffracted to about 9-12 Å resolution (Refs 6,7). The diffraction limit of these crystals did not improve beyond 7 Å resolution for almost a decade, but more recently both Yonath and coworkers (Refs 8,9) and we (Ref 3) obtained crystals of the MPD form that exhibit significantly  
15 improved diffraction. However, unlike the crystals obtained by the Yonath group (Ref 9), our crystals do not require soaking in tungsten clusters or heat treatment in order to obtain high resolution diffraction.

Last year, we described the structure of the 30S at 5.5 Å  
20 resolution (Ref 12). We were able to place all seven proteins whose structures were known at the time, infer the structure of protein S20 to be a three-helix bundle, trace the fold of an entire domain of 16S RNA, and identify a long RNA helix at the interface that contains the decoding site of the 30S. Proteins  
25 S5 and S7 were also placed in electron density maps of the 30S obtained by Yonath and coworkers.

The 30S ribosomal subunit is a major target for antibiotics. The ribosome is a useful target for antibiotics since the structure of the 30S is widely conserved between prokaryotes,  
30 allowing for broad spectrum antibiotics. However, resistance to current antibiotics is currently a major problem in the field of medicine. There are presently very few new antibiotics available which can be used to treat the highly resistant strains of bacteria such as MRSA (methicilin resistant  
35 *Staphylococcus aureus*) which are becoming increasingly widespread.

Understanding the interaction of antibiotics with the ribosome at the molecular level is important for two reasons. Firstly, antibiotics act by interfering with various aspects of ribosome function. Thus understanding their interaction will help shed  
5 light on mechanisms involved in translation. Secondly, a detailed knowledge of antibiotic interactions with the ribosome could aid the development of new drugs against increasingly resistant strains of bacteria. Although antibiotics were characterized several decades ago, a detailed knowledge of their  
10 mechanism will in general require a three-dimensional structure of their complex with the ribosome.

The low (greater than 3Å resolution) crystal structures described above do not provide sufficiently detailed resolution for useful modelling of the crystal structure of the 30S and  
15 there is thus a need for a high resolution structure which can be used usefully in the development of novel therapeutics.

#### Summary of the Invention

We have now solved and refined the structure of the 30S at 3 Å resolution. The structure contains all of the ordered regions of  
20 16S RNA and 20 associated proteins, and contains over 99% of the RNA sequence and 95% of the protein sequences, with the missing parts being exclusively at the termini of RNA or polypeptide chains. Here we describe the overall architecture and the main structural features of the 30S subunit. In accompanying  
25 examples, we further describe functional insights gleaned from the structure and the location of antibiotics bound to the 30S.

In a first aspect, the present invention provides a crystal of the *Thermus thermophilus* 30S subunit having a tetragonal space group  $P4_12_12$  with unit cell dimensions of  $a = 401.375$ ,  $b =$   
30  $401.375$ ,  $c = 175.887$  Å, or more generally,  $a=401.4 \pm 0.7$ ,  $b=401.4 \pm 0.7$ ,  $c=175.9 \pm 0.7$  Å. Such a structure includes the 30S crystal of Table 2 which is bound to antibiotics. This has unit cell dimensions of  $a= 402.001$ ,  $b= 402.001$   $c =176.489$ . An  
35 advantageous feature of the structure is that it diffracts beyond 3Å resolution. Another feature of the structure is that it was obtained in a method which did not involve the use of

heavy atom clusters or heat activation. Furthermore, it is specifically of the 885-888/910-912 base pairing confirmation of 16S RNA. These features, both singly and in combination all contribute to features of the invention which are advantageous.

- 5 In a second aspect, the invention also provides a crystal of 30S having the three dimensional atomic coordinates of Table 1 or Table 2, the data of Table 2 optionally further including the data of one or more of Tables 3 to 5.

- 10 The coordinates of Tables 1 to 5 provide a measure of atomic location in Angstroms, to a third decimal place. In order to use the information in these Tables for the purposes described herein as being aspects of the present invention, these coordinates may be varied by  $\pm 0.7$ , preferably no more than  $\pm 0.5$  Angstroms, without departing from the scope of the invention.
- 15 Reference herein to the use of the coordinates of any one of Tables 1 to 5 thus includes the use of coordinates in which one or more individual values of the Tables are adjusted by this amount.

- 20 We have also observed that 30S crystals do not contain the S1 subunit protein. In our studies, we have found that by selectively removing this protein prior to crystallization, we have been able to obtain the improved resolution described herein. Although the atomic co-ordinates provided in Tables 1 and 2 (the data of Table 2 optionally including one or more of
- 25 the data of Tables 3 to 5) below allow those of skill in the art to bypass the need to undertake the crystallization of the 30S, this crystallization method nonetheless forms a further aspect of the invention.

- 30 Accordingly, there is provided a method for crystallizing a the 30S subunit to obtain a high resolution structure of a 30S subunit, which method comprises providing a 30S subunit, selectively removing the S1 subunit therefrom and crystallizing the 30S. The crystallization conditions may comprises the use of 13-17% methyl-2,4-pentanediol in the presence of 250 mM KCl,
- 35 75 mM ammonium chloride, 15 mM  $MgCl_2$  at a pH of 6.5 in sodium cacodylate or MES (2-(N-morpholino)ethane sulphonic acid). In

another aspect, the conditions may comprise the use of 250 mM KCl, 75 mM NH<sub>4</sub>Cl, 25 mM MgCl<sub>2</sub>, 6 mM 2-mercaptoethanol in 0.1 M potassium cacodylate or 0.1 M MES (2-N-morpholino-ethanesulfonic acid) at pH 6.5 with 13-17% MPD as the precipitant.

- 5 Crystals may be grown over a period of 4-8 weeks at about 4°C. Crystals obtainable by such a method are also a further aspect of the invention.

10 This methodology provides those of skill in the art a means to provide 30S crystals of *T.thermophilus*. The conservation of ribosome structure, particularly regions of structure essential for function, between prokaryotes, for example prokaryotes which are human pathogens, such as *Staphylococcus* spp, and the like, allows the structure herein to be useful in the provision of anti-bacterial agents in general.

- 15 The crystals may be grown by any suitable method known as such to those of skill in the art. The structure of the crystals so obtained may be resolved to a resolution of at least 3Å.

20 In a further aspect, the present invention provides a method for identifying a potential inhibitor of the 30S comprising the steps of:

- a. employing a three-dimensional structure of 30S, or at least one sub-domain thereof, to characterise at least one active site, the three-dimensional structure being defined by atomic coordinate data according to Table 1 or 2 (the data of Table 2 optionally including one or more of the data of Tables 3 to 5); and

b. identifying the potential inhibitor by designing or selecting a compound for interaction with the active site.

The term "sub-domain" includes the following:

- 30 at least one complete element of secondary structure, i.e. an alpha helix or a beta sheet, or RNA helix, as described in the detailed description below;

a group of two or more such elements which interact with each other (including for example the subgroups of helices shown in any one of Figures 3 to 6);

at least one subunit protein;

a subgroup of subunit proteins, for example a group which includes two or more proteins which are found to interact with each other;

- 5       any of the above, when being protein or element thereof being used in conjunction with all or part of the 16S RNA structure associated with said elements or proteins.

10       A subdomain also includes a space of volume defining a region around any one particular atom of interest (e.g. an atom involved in binding to an antibiotic), the volume being less than the total volume of the tetragonal space of the complete crystal. For example, the coordinates of atoms in a volume of from about 500 to about 15,000 Å<sup>3</sup> may be selected and used for the present invention. Such a space may be a sphere having a  
15       diameter of from about 10Å to about 30Å, centred around a point of interest.

20       An active site of the 30S is any part of this structure involved in tRNA or mRNA binding, synthesis or translocation, including regions of the complex not directly associated with tRNA or mRNA binding but which are required for the ribosome to function, for example those regions which undergo structural changes associated with protein synthesis or are target sites for regulation by co-factors, phosphorylation or acetylation.

25       Particular regions of the 30S include those identified herein as antibiotic binding regions based on the data provided in Tables 2 to 5. Other regions include the three tRNA sites, i.e. the aminoacyl (A), peptidyl (P) and (exit) E sites. Other active sites are those which undergo movement during translocation of tRNAs from the A to P sites and the P to E sites.

30       Regions further include any one of the subunit proteins S2 to S21, including any of the individually identified subunit proteins in the accompanying examples.

35       Table 1 includes coordinates of two zinc ions, together with 202 other ions which are not identified, although, while not wishing to be bound by any one theory, are believed to be selected from

cobalt and magnesium. Some or all of these ions may optionally be discarded from Table 1 when using the data. The table also lists the coordinates of a 26 amino acid peptide, Thx, as well as a 6 nucleotide fragment of mRNA, NNNUCU, designated as molecule X. Both the coordinates of both these molecules may likewise optionally be discarded, i.e so that the coordinates of the 16S mRNA and the proteins S1 to S20 alone are modelled and used in applications of the invention.

Likewise, table 2 provides the coordinates of two zinc ions, together with 96 ions which in this crystal have been identified as magnesium. Some or all of these may optionally be disregarded, as well as (either together with or separately) one or both of the mRNA fragment and the Thx peptide.

There are a few N- or C-terminal sequences of the S2 to S20 proteins which were not resolved in the structure of Table 1, together with a some of the 5' and 3' residues of the 16S RNA. These are not essential for the purposes of the present invention, but are listed in Table 6 for completeness. Those of skill in the art may, if desired, wish to adapt the structures provided by the coordinate of Table 1 by modelling in one or more of the amino acids or nucleotides of Table 6. This may also be the case for Table 2. In addition, there are 8 amino acids identified in Table 1 which were not resolved in Table 2. These are: Glu B 241, Ala B 242, Glu B 243, Ala L 129, Gly S 82, His S 83, Gly S 84 and Lys S 85. The coordinates of these residues of Table 1 may be adapted, if desired, for introduction into Table 2.

In any event, the determination of the three-dimensional structure of 30S provides a basis for the design of new and specific ligands for 30S. For example, knowing the three-dimensional structure of 30S, computer modelling programs may be used to design different molecules expected to interact with possible or confirmed active sites, such as binding sites or other structural or functional features of 30S.

Paromomycin is an aminoglycoside antibiotic. Other antibiotics of this class include gentomycin and neomycin. In one aspect,

the coordinates provided in Tables 1-3 may be used to examine the binding to the 30S to other aminoglycoside antibiotics, so that common binding features may be determined and used as a basis for rational drug design.

- 5 The high resolution model of the 30S provided by Tables 1 and 2 may be used to examine and determine the binding of other antibiotics known to target this ribosome subunit. Such antibiotics include tetracyclin.

10 More specifically, a potential modulator (including antibiotics and derivatives thereof) of 30S activity can be examined through the use of computer modelling using a docking program such as GRAM, DOCK, or AUTODOCK (see Walters et al., *Drug Discovery Today*, Vol.3, No.4, (1998), 160-178, and Dunbrack et al., *Folding and Design*, 2, (1997), 27-42) to identify potential  
15 inhibitors of 30S. This procedure can include computer fitting of potential inhibitors to 30S to ascertain how well the shape and the chemical structure of the potential inhibitor will bind to the ribosome.

20 Also computer-assisted, manual examination of the active site structure of 30S may be performed. The use of programs such as GRID (Goodford, *J. Med. Chem.*, 28, (1985), 849-857) - a program that determines probable interaction sites between molecules with various functional groups and the enzyme surface - may also be used to analyse the active site to predict partial structures  
25 of inhibiting compounds.

Computer programs can be employed to estimate the attraction, repulsion, and steric hindrance of the two binding partners (e.g. the 30S and a potential inhibitor). Generally the tighter the fit, the fewer the steric hindrances, and the greater the  
30 attractive forces, the more potent the potential modulator since these properties are consistent with a tighter binding constant. Furthermore, the more specificity in the design of a potential drug, the more likely it is that the drug will not interact with other proteins as well. This will tend to minimise potential  
35 side-effects due to unwanted interactions with other proteins.

Having designed or selected possible binding partners, these can then be screened for activity. Consequently, the method preferably further comprises the further steps of:

- c. obtaining or synthesising the potential inhibitor; and
- 5        d. contacting the potential inhibitor with 30S to determine the ability of the potential inhibitor to interact with 30S.

More preferably, in step d. the potential inhibitor is contacted with 30S under conditions to determine its function, for example in a cell free translation system.

- 10        Instead of, or in addition to, performing such an assay, the method may comprise the further steps of:

- c. obtaining or synthesising said potential inhibitor;
  - d. forming a complex of 30S and said potential inhibitor;
  - and
  - 15        e. analysing said complex by X-ray crystallography to determine the ability of said potential inhibitor to interact with 30S. Detailed structural information can then be obtained about the binding of the potential inhibitor to 30S, and in the light of this information adjustments can be made to the
  - 20        structure or functionality of the potential inhibitor, e.g. to improve binding to the active site. Steps c. to e. may be repeated and re-repeated as necessary.

- 25        Another aspect of the invention includes a compound which is identified as an inhibitor of 30S by the method of the above aspects of the invention.

- 30        In another aspect, the invention provides a method of analysing a 30S-ligand complex comprising the step of employing (i) X-ray crystallographic diffraction data from the 30S-ligand complex and (ii) a three-dimensional structure of 30S, or at least one sub-domain thereof, to generate a difference Fourier electron density map of the complex, the three-dimensional structure being defined by atomic coordinate data according to Table 1 or 2 (the data of Table 2 optionally including one or more of the data of Tables 3 to 5).

- 35        Therefore, 30S-ligand complexes can be crystallised and analysed

using X-ray diffraction methods, e.g. according to the approach described by Greer et al., *J. of Medicinal Chemistry*, Vol. 37, (1994), 1035-1054, and difference Fourier electron density maps can be calculated based on X-ray diffraction patterns of soaked  
5 or co-crystallised 30S and the solved structure of uncomplexed 30S. These maps can then be used to determine whether and where a particular ligand binds to 30S and/or changes the conformation of 30S.

Electron density maps can be calculated using programs such as  
10 those from the CCP4 computing package (Collaborative Computational Project 4. The CCP4 Suite: Programs for Protein Crystallography, *Acta Crystallographica*, D50, (1994), 760-763.). For map visualisation and model building programs such as "O" (Jones et al., *Acta Crystallography*, A47, (1991), 110-119) can be  
15 used.

In a further aspect, the present invention provides computer readable media with either (a) atomic coordinate data according to Table 1 or 2 (the data of Table 2 optionally including one or more of the data of Tables 3 to 5) recorded thereon, said data  
20 defining the three-dimensional structure of 30S or at least one sub-domain thereof, or (b) structure factor data for 30S recorded thereon, the structure factor data being derivable from the atomic coordinate data of Table 1 or 2 (the data of Table 2 optionally including one or more of the data of Tables 3 to 5).

25 As used herein, "computer readable media" refers to any media which can be read and accessed directly by a computer. Such media include, but are not limited to: magnetic storage media such as floppy discs, hard disc storage medium and magnetic tape; optical storage media such as optical discs or CD-ROM;  
30 electrical storage media such as RAM and ROM; and hybrids of these categories such as magnetic/optical storage media.

By providing such computer readable media, the atomic coordinate data can be routinely accessed to model 30S or a sub-domain thereof. For example, RASMOL is a publicly available computer  
35 software package which allows access and analysis of atomic coordinate data for structure determination and/or rational drug

design.

On the other hand, structure factor data, which are derivable from atomic coordinate data (see e.g. Blundell et al., in *Protein Crystallography*, Academic Press, New York, London and San Fransisco, (1976)), are particularly useful for calculating e.g. difference Fourier electron density maps.

In another aspect, the present invention provides systems, particularly a computer systems, intended to generate structures and/or perform rational drug design for 30S or 30S ligand complexes, the systems containing either (a) atomic coordinate data according to Table 1 or 2 (the data of Table 2 optionally including one or more of the data of Tables 3 to 5), said data defining the three-dimensional structure of 30S or at least one sub-domain thereof, or (b) structure factor data for 30S, said structure factor data being derivable from the atomic coordinate data of Table 1 or 2 (the data of Table 2 optionally including one or more of the data of Tables 3 to 5).

Examples of such systems are microcomputer workstations available from Silicon Graphics Incorporated and Sun Microsystems running Unix based, Windows NT or IBM OS/2 operating systems.

As used herein, "a computer system" refers to the hardware means, software means and data storage means used to analyse the atomic coordinate data of the present invention. The minimum hardware means of the computer-based systems of the present invention comprises a central processing unit (CPU), input means, output means and data storage means. Desirably a monitor is provided to visualise structure data. The data storage means may be RAM or means for accessing computer readable media of the invention.

The present high resolution structure of 30S provides a means to address the problems of antibiotic resistance in prokaryotes which are resistant to antibiotics known to act on the 30S, including paromomycin, streptomycin and spectinomycin. The data of Table 2 in conjunction with one or more of the data of Tables

3 to 5 provides high resolution of the site of action of these antibiotics. Mutant strains resistant to the action of these antibiotics can arise through mutation of a protein subunit of the 30S or through mutation in the 16S RNA. As indicated in the accompanying examples, the sites of mutations in some cases are known or can be identified. Where such sites are identified through, for example, primary sequence data, the invention provides a means to model the structure of the mutants.

There is thus provided a method which comprises providing the structure of the 30S ribosome of Table 1 or Table 2 (the data of Table 2 optionally including one or more of the data of Tables 3 to 5), changing one amino acid or nucleotide of said structure to provide a mutant 30S, and modelling the structure of the mutant 30S to provide a structure of the mutant. The mutant may be used in the manner described above for the wild type, e.g. stored in computer readable form, modelled to provide ligands, and the like. The modelling may be based upon the predicted behaviour of the atoms of the changed amino acid based upon its interaction with the surrounding atoms in the model provided herein.

This process may be iterative, e.g. to produce successive mutations into the 30S structure, for example 2, 3, 4, or 5 to 10 mutations.

Regions of 30S which may be subject to this aspect of the invention include those regions identified in the accompanying examples as regions of the 30S involved in ribosome function or in resistance to antibiotics.

The invention is illustrated below by the following examples 1 and 2, their accompanying Figures and the tables 1 to 7. In Tables 1 and 2, there is shown in each row Atom number, element type, residue (amino acid, nucleotide, etc), number in molecule (for proteins N to C terminal direction, for nucleic acid 5' to 3' direction), X, Y and Z co-ordinates, occupancy, B factor ( $\text{\AA}^2$ ) and an identifier for the member of the 30S (e.g. for the subunits in the format "A"S"n" where A is an arbitrary letter, different for each member, S is the subunit and n is the subunit

number; and for the 16S as "A16S"). Tables 3 to 5 provide the X, Y and Z coordinates of the defined atoms of the antibiotics mentioned therein. Table 6 provides a list of residues not identified in the analysis.

## 5 Description of the Drawings.

Fig. 1. Secondary structure diagram of 16S RNA (modified from ref. 53), showing the definition of the various helical elements used throughout the text. The numbering and diagram correspond to the E. coli sequence.

- 10 Fig. 2. Different modes of interhelical packing in the 16S rRNA.  
(a) The common minor-groove to minor-groove packing mode is often stabilized by a layer of adenosines, which mediate most of the hydrogen bonds between two helices. (b) The phosphate ridge to minor groove mode. Usually this mode is stabilized by  
15 hydrogen bonds between guanine N2 groups and phosphate oxygens.  
(c) The rare end-on mode of packing uses an unpaired purine (leftmost base) to mediate packing of two helices at right angles to each other.

subunit. A chemical diagram for paromomycin, showing interactions of the various groups with specific residues of the 30S.

### Example 1

5 The crystal structure of the 30S ribosomal subunit has been solved and refined to 3 Å resolution. The final atomic model rationalizes over four decades of biochemical data on the ribosome, and provides a wealth of information about RNA and protein structure, protein-RNA interactions and ribosome  
10 assembly. It also provides a firm structural basis for the analysis of functional roles of the 30S subunit such as decoding, and for understanding the basis of antibiotic action. The structure will also provide the basis for interpretation of lower resolution structural data on functional states of the  
15 ribosome from electron microscopy and crystallography.

#### Materials and Methods:

##### Crystallization of the 30S

Crystals were obtained by a straightforward optimization of Trakhanov et al (Ref 6) with respect to pH, and concentrations  
20 of  $Mg^{2+}$  ions and MPD. The final conditions were 250 mM KCl, 75 mM  $NH_4Cl$ , 25 mM  $MgCl_2$ , 6 mM 2-mercaptoethanol in 0.1 M potassium cacodylate or 0.1 M MES (2-N-morpholino-ethanesulfonic acid) at pH 6.5 with 13-17% MPD as the precipitant. It was noticed initially that the 30S crystals completely lacked ribosomal  
25 protein S1, so care was taken to remove S1 selectively from the 30S prior to crystallization, which improved both size and reproducibility. Crystals took approximately 6 weeks at 4 °C to grow to their maximum size. The largest crystals, which were required for high resolution data collection, grew to a size of  
30 80-100 × 80-100 × 200-300 microns. The activity of redissolved crystals in poly(U)-directed protein synthesis was comparable to that of freshly isolated 30S subunits.

##### Data collection

Crystals were transferred to 26% MPD by vapor diffusion in two  
35 steps over a period of 6 days. All solutions (except for those containing osmium hexammine or osmium pentammine) also contained

1 mM cobalt hexammine in the cryoprotectant. Crystals were flash-cooled by plunging into liquid nitrogen, and data collection was done in a cryostream at 90-100 K.

- 5 A large fraction of crystals was screened at beamlines 9.6 or 14.1 at the SRS at Daresbury Laboratories, using two short exposures at least 40 degrees apart. These crystals were then analysed for diffraction limits, cell dimensions and mosaic spread. Only crystals of similar cell dimensions and with reasonable mosaic spread were used for data collection.
- 10 Potential derivatives were screened on beamlines X25 at the NSLS at Brookhaven National Laboratory and BM-14 at the ESRF (Grenoble). Data to about 4.5 Å were obtained from X25. High resolution data were collected at SBC 19ID at the APS in Argonne National Laboratory, and ID14-4 at the ESRF. In all cases,
- 15 derivative data were collected at the peak of the fluorescence at the LIII edge to maximize anomalous differences. At X25 and SBC 19ID, the kappa goniostat was used to rotate precisely about a mirror plane so that small anomalous differences could be measured accurately despite radiation decay and the use of
- 20 multiple crystals. Each crystal typically yielded 3-10 degrees of data. Data were integrated and scaled using HKL-2000 (Ref 13).

#### Structure determination

- 25 Previously determined phases at 5.5 Å (Ref 12) were used to locate heavy atom sites using anomalous difference Fourier maps. Initially, these sites were used for phasing to 3.35 Å using the program SOLVE (Ref 14) followed by density modification with SOLOMON (Ref 15) using the procedure implemented in SHARP (Ref 16). Optimization of the various parameters in the procedure was
- 30 required to obtain interpretable maps. The RNA and some of the proteins were built using the SOLVE maps. The sequence of *Thermus thermophilus* 16S RNA (Ref 17) and both previously available and unpublished (Göttingen Thermus Genome Sequencing Project) sequences for the proteins were used to build the
- 35 structure. Improved maps were obtained by calculating experimental phases using SHARP followed by density modification and phase extension to 3.05 Å with SOLOMON and DM

(Ref 18). The improved maps allowed us to build all the remaining ordered parts of the structure. The model was built using O (Ref 19), and refined using the program CNS (Ref 20). Maximum likelihood refinement was used, initially with both  
5 amplitudes and experimental phase probability distributions to 3.35 Å, and subsequently with amplitudes to 3.05 Å.

### Results

The 30S subunit from *Thermus thermophilus* consists of a 1522 nucleotide 16S ribosomal RNA and 21 associated proteins, of  
10 which 20 have known counterparts in *E. coli*. Protein S21 is not present in *Thermus*, and protein S1 has been removed from the 30S prior to our crystallization. In addition, a 26 residue peptide, Thx, is present in *Thermus* 30S subunits.

The quality of the data and phasing statistics are shown in  
15 Table 7. Experimentally phased maps clearly showed main chain density for RNA and protein, individual bases (which were often of sufficient quality to distinguish purines from pyrimidines), and large well-ordered side chains of proteins. These maps were used to build 16S RNA and the previously unknown proteins S2,  
20 S3, S9, S10, S11, S12, S13, S14 and Thx. In addition, regions that were disordered in isolated structures or had changed significantly were also built. This often consisted of significant portions of the N- and C-terminal tails of the proteins, sometimes including entire domains that were unfolded  
25 in isolation. Proteins with small cores and long loops, such as S16 and S17, had to be substantially rebuilt, since these loops were generally disordered in the solution NMR structures. Finally, the entire structure was rebuilt after an initial round of refinement. Our current model consists of nucleotides 5-1511  
30 of *Thermus thermophilus* 16S RNA (corresponding to 5-1534 of *E. coli* 16S RNA) and all of the ordered regions of the associated 20 proteins. The current model has been refined against 3.05 Å data with a conventional R-factor of 0.213, a free R-factor of 0.256 and good geometry. For the proteins, 94% of the residues  
35 were in the core or allowed regions of the Ramachandran plot, 3.9% in the generously allowed region and 1.8% in the disallowed region.

### Overview of the 30S subunit

Throughout this application, the numbering system for E.coli 16S RNA is used, as well as the standard helix numbering, denoted H1-H45, for the secondary structure elements with some  
5 modifications as shown in Fig 1. The most significant differences between the E.coli and T. thermophilus sequences are a shorter H6 and H10, and insertions in H9 and H33a. Any insertions in T. thermophilus relative to E. coli are indicated in the coordinates with an insertion letter after the nucleotide  
10 number, following the practice for tRNA.

The overall shape of the 30S is very similar to the classical model derived from negatively stained EM samples and to more recent cryo-EM reconstructions. The standard view, shown in Fig. 1b, clearly shows the head with a beak pointing leftwards, and a  
15 body with the platform to its top right and shoulder to its top right. These features have nearly identical shapes to their EM counterparts. The overall shape of the subunit is determined by the shape of the RNA component; none of the gross morphological features are all protein. As seen in Fig. 1b, individual  
20 secondary structure domains make up each of the morphological features, a feature which was also deduced in previous modelling studies. The 5' domain (fpd) makes up the bulk of the body; the central domain (cd) is most of the platform; and the 3' major domain (tpd) constitutes the bulk of the head. The 3' minor  
25 domain (tmd) is the only significant exception to this rule, as it is part of the body at the subunit interface.

The four domains of the 16S rRNA secondary structure radiate from a central point (Fig. 1c and d). In the crystal structure, this central point is found in the neck region of the subunit,  
30 around the base of the head. The four domains are especially tightly associated in this area. The W-shaped central domain wraps its outer arms around the fpd and tmd domains. The long arm of the central domain reaches around and packs against fpd. The other outer arm of the central domain wraps around the tmd.

### The structure of the RNA

The secondary structure of 16S ribosomal RNA contains forty-five double helices connected by short single-stranded segments. In

the crystal structure, many of these helices are coaxially stacked with a helix neighboring in the sequence. There are 13 groups of coaxially stacked helices and 23 unstacked helices in 16S rRNA, for a total of 36 helical elements. There are three different types of helix-helix packing. Most of the helical elements are packed in a minor groove to minor groove fashion, which often requires distortions from canonical A-form helical geometry in one of the two helices. Adenosines from internal loops or from hairpin loops often mediate docking against an A-form double helix, with a dense network of base-2' OH and 2' OH - 2' OH hydrogen bonds stabilising the packing (Fig. 2a). Less often, helix-helix packing occurs in a different mode, by insertion of a ridge of phosphates into a complementary minor groove of another helix (Fig. 2b). This packing mode is stabilized by hydrogen bonds between the ridge of phosphate oxygens and a layer of 2' OH and guanine base NH<sub>2</sub> groups. These guanine N2 groups are often made more accessible by the geometry of G-U pairs, which places this moiety farther into the minor groove than do Watson-Crick pairs. Finally, the rare end-on mode of interhelical packing uses a purine base to mediate the perpendicular packing of one helix against the minor groove of another helix (Fig. 2c). All three modes of helix-helix packing are further stabilized by idiosyncratic interactions between double-helical RNA and short non-helical RNA segments. Small bulges of one to three nucleotides are often found to pack either between helices or in the major groove of a helix.

#### The 5' domain (fpd)

The fpd of 16S RNA contains 19 double helices (Fig. 3), arranged as 7 groups of coaxially stacked helices and 5 unstacked helices, for a total of 12 double-helical elements packed tightly together. The result is a wedge-shaped mass of RNA that tapers to a single layer of double helices near the top of the domain. Like the other domains, the fpd is rather longer along the subunit interface than in the perpendicular direction.

The fpd can be divided into three subdomains, roughly corresponding to the upper, lower, and middle thirds of the secondary structure of the fpd. These subdomains make up the top and left-hand, the middle, and the lower right-hand sides of the

body, respectively, in the view from 50S. The upper subdomain is a nearly planar arrangement of four helical elements (H16/H17, H4/H15, H1/H3, and H18). The H16/H17 stack forms the left-hand border of the body as viewed from 50s. This stack is almost 120 Å long, with H16 making contact with the head and H17 reaching the bottom of the subunit. Internal loops in both helices contain S-turns, which are used to modulate the position of the phosphate backbone in the case of H17, or to create an extended minor groove surface for helix-helix docking in the case of H16. The H4/H15 stack points towards the bottom of the subunit, with H15 well-packed against H17. The H1/H3 stack is bent by the conserved bulge at position 31, which results in the proximal end being horizontal and the terminal end pointing up to the head. The fourth helical element is H18, which is sharply bent to accommodate the 530 pseudoknot, defined by the unstacked helices 505-507/524-526 (H18.2) and 521-522/527-528 (H18.1). H18 is well-packed between the other two upwards-pointing elements of the upper subdomain, H1/H3 and H16. The 530 pseudoknot packs against the central pseudoknot at the H18.1 - H1 interface.

The middle subdomain contains four helical elements (H5, H6, H12/H6A, and H13/H14) that form a layer between the upper and lower subdomains in the centre of the body. There are relatively few packing interactions within the subdomain, and several of its helices pack against the upper subdomain on one side and the lower subdomain on the other. Thus at the bottom of the subunit, the conserved root of H6 packs against H8 (lower subdomain) on one side and H15 (upper subdomain) on the other side. Similarly, the H12/H6A stack packs against H4 (upper subdomain) and H7 (lower subdomain). H12/H6A also packs against H5 and the 117 loop, which pack against elements from the upper and lower subdomains, respectively. H5 is well-packed against H15 and the 117 loop stacks with the root of H11. H5 also packs against the H13/H14 stack in the phosphate ridge-minor groove manner. H13/H14 interacts with two different regions of the lower subdomain. The conserved UACG hairpin loop at the end of H14 packs against the 160 GAAA hairpin from H8 while the large conserved hairpin at the end of H13 interacts with H7. This hairpin loop also makes many interactions with elements from the middle subdomain.

The lower subdomain is a collection of three helical elements that form an open saddle-shaped structure in the lower right-hand corner of the body. The H8/H9 stack stretches from the back of the subunit to the front, with the conserved 160  
5 GAAA hairpin pointing toward the 50S subunit. It packs tightly against the H7/H10 stack at the 4-way junction that joins them, and again at a Thermus-specific interaction between insertions at nucleotides 190 and 129. The H7/H10 stack also makes weak  
10 interactions with H15 and H17 from the upper subdomain at the bottom of the subunit. H11 contains two sharp bends that allow its conserved terminal hairpin loop to pack against H7. Both bends are stabilized by short-range minor-groove to minor-groove packing contacts.

The central domain (cd)

15 The cd is the RNA component of the platform. Its fold based on our previous 5.5 Å structure (Ref 12) is in excellent agreement with our current structure (Fig. 4). It contains nine helical elements folded into a W-shape in the 50S view. Two long  
20 single-stranded segments of RNA, the 570 and 820 loops, are also important structural elements. The domain is dominated by the long stack of H21/H22/H23, which forms the U-shaped perimeter of the domain. H21 is the only component of the left-hand arm of the W, while H22 and H23 form the base of the right-hand side. The right-hand arm of the W consists of H23B and H24A whose  
25 conserved hairpin loops are tightly packed. This arrangement requires sharp bends between H23 and H23B, and between H24 and H24A. The H23/H23B bend is stabilized by short-range minor groove-minor groove packing interactions. The H24/H24A bend is more unusual in that the bend is towards the major groove, which  
30 places a ridge of H24A phosphates in the major groove of H24. This major-groove bend is stabilized partly by short-range base-base and base-backbone interactions in the major groove of the bend, and partly by long-range interactions between the bent H24/H24A minor groove and the minor groove of H23. The heart of  
35 the central domain is the thicker middle arm of the W, which contains six helical elements (H20, H19/H25, H24, H26/H26A, H27, and H23B) and the 570 and 820 loops. On the left-hand side of the arm, the H26/H26A stack packs tightly against H22, the base of H25, and the 570 loop. The H25/H19 stack packs well with H20

and with the 570 loop. On the right-hand side of the central arm of the W, H23A packs well with H22, the 820 loop stacks on H24, and H24 packs well with the conserved GCAA hairpin loop of H27. In the centre of the arm, H23A packs with H26 in the phosphate  
5 ridge-minor groove manner, and the conserved H23A GAAG hairpin loop packs against H20. The 820 loop also interacts with H20, H25, and the 570 loop.

The 3' major domain (tmd)

The 3' major domain (tpd) is the RNA component of the head of  
10 the 30S subunit. From the 50S view, the left-hand side of the head tapers to a beak made of RNA on the 50S side and protein on the solvent side (Fig. 5). Like the other domains, the tpd is relatively thin in the direction perpendicular to the intersubunit interface. The tpd consists of fifteen helical  
15 elements, most of which do not stack on a neighboring helix, in contrast to the extensive stacking of neighboring helices seen in the fpd and the central domain. The tpd can be divided into three subdomains, which correspond to the upper, middle, and lower portions of the tpd secondary structure. The upper  
20 subdomain is an extended structure in the part of the head farthest from the 50S subunit, and makes relatively few packing contacts with RNA from the other head subdomains. The lower and middle subdomains are more globular and are more intimately packed together, and make up the front-right and front-left  
25 portions of the head, respectively. The middle subdomain includes the RNA portion of the beak.

The upper subdomain contains three helical elements that make up a well-separated structure on the solvent side of the head. The subdomain is dominated by the H35-H36-H38-H39 stack, which  
30 stretches from the top to the bottom of the head. The other two helical elements of this subdomain are H37 and H40, which pack well with each other and loosely with the H35-H36-H38-H39 stack. The H37-H40 pack is mediated by a semiconserved GAAA hp in H40 with adjacent G-C pairs in H37.

35 The smaller middle subdomain is extended and contains only four helical elements, H32, H33/H33A, H33B and H34. Two of these (H33/H33A and H33B) form the Y-shaped RNA component of the beak.

The H33/H33A stack points to the left in the 50S view while H33B points to the right, with its terminal conserved GNRA hairpin loop packed against H32, the covalent connection between the beak and the lower subdomain. H32 in turn packs against the H33-H34 junction as well as the 980 loop in the lower subdomain. With the exception of a small packing interaction with H32, the irregular H34 makes only long-range and somewhat tenuous packing interactions. The first is with H31 in the lower subdomain, an unusually weak minor-groove to minor groove packing. The second interaction is an unusual end-on packing interaction with the minor groove of the H34/H35/H38 junction in the upper subdomain.

The lower subdomain contains almost half of the tpd RNA and contains seven helical elements (H28/H29, H30, H31/980 loop, H41, H41A, H42 and H43) intimately packed into a globular mass. Helices 42 and 43 are arranged in an approximately parallel fashion at the center of the fold, and each interacts with at least three of the the other helical elements. Helices 42 and 43 dock together by means of a minor-groove to minor-groove packing of their conserved hairpin loops. On the solvent side of the H42/H43 pair, H41 packs with both H42 and H43, while the terminal GCAA hairpin loop of H41A packs against H42. This arrangement requires a sharp bend between H41 and H41A, whose minor grooves pack against each other at the bend. The H43-H41 pack is made more extensive by an underwound A-rich internal loop in H41. On the 50S side of the central H42/H43 pair are H29, H30, H31 and the 980 loop. H43 is well-packed with H29 and makes weaker interactions with H30 and the 980 loop, while H42 is well-packed with H30 and the 980 loop. The H42-H30 pack is mediated by successive conserved G-A pairs at the base of H42. The H43-H29 pack is mediated by a conserved S-turn at the base of H43. An S-turn also mediates the packing of H42 with H41. H31 is a peripheral element of the subdomain, packing well only with H30, but also packs with H34 from the middle subdomain.

### The 3' minor domain

The 3' minor domain consists of just two helices at the subunit interface (Fig. 6). H44 is the longest single helix in the subunit, and stretches from the bottom of the head to the bottom of the body. It projects prominently from the body for

interaction with the 50S subunit. H45 is approximately perpendicular to H44, with its conserved GGAA hairpin loop packed against H44 and available for interaction with the large subunit.

5 Proteins in the 30S and their interaction with 16S rRNA

The current structure includes all of the 30S proteins except S1. The proteins generally consist of one or more folded domains, about half of which were known from previous work on isolated proteins 26. However, nearly all of the proteins  
10 contain extended termini or loops which interact intimately with RNA and were disordered in the isolated structures. Although most of the proteins form intimate contacts with ribosomal RNA, there are also protein-protein interactions such as those seen in the S4-S5-S8 and S3-S10-S14 clusters. Finally, we see the  
15 same folds, e.g. a/b folds, used to interact with RNA in different ways, making prediction of mode of RNA binding from topology difficult.

In general, prior biochemical data on hydroxyl-radical footprinting (Refs 27) and crosslinking (Refs 28,29) (see also  
20 summaries in ref. 22 #39 and [www.mpimg-berlin-dahlem.mpg.de/~ag\\_ribo/ag\\_brimacombe/drc](http://www.mpimg-berlin-dahlem.mpg.de/~ag_ribo/ag_brimacombe/drc) ) agree well with the structure, and were useful as a guide to interpreting the fold at lower resolution. However, while a strong hydroxyl-radical footprint is indicative of contact, the converse is not true  
25 because extensive interactions often occur via the major groove or the phosphate backbone. Earlier base footprinting methods show poor correlation to structural contacts. Similarly, the residues in UV-induced crosslinks are generally found close together, but generally not those crosslinked using other  
30 reagents.

Proteins in the 30S and their interaction with 16S RNA.

The proteins of the 30S generally consist of one or more folded domains. The same types of folds are frequently found in different proteins, such as the  $\beta$ -barrel in S12 and S17, and  
35  $\alpha$ -helices packed against a  $\beta$ -sheet as observed in S3, S10, S6, and S11. It is interesting that these domains often interact with RNA in very different ways. The  $\beta$ -sheet of S11 packs flat

against the minor groove of RNA, while in S6 the edge of the sheet interacts with RNA. In S3 one of the a/b domains makes no contact with RNA at all.

5 In addition to a globular domain nearly all the proteins contain long extensions. These can be helical such as the a-hairpin in S2 or the C-terminal helices in S13; long b-hairpins or loops protruding from S10 or S17; or extended C or N terminal tails seen in proteins S4, S9, S11, S12, S13 and S19. These extensions make intimate contact with RNA, and were generally  
10 not visible in isolated structures because they were disordered in the absence of RNA. The extensions reach far into the surrounding RNA, and allow single proteins to contact multiple RNA elements, which is probably important for the stabilization of the RNA tertiary fold. The extensions are particularly well  
15 suited for this task because being narrow they can allow close approach of different RNA elements, while providing the basic residues required to neutralize the charge repulsion of the RNA backbone. An extension of this principle is seen in Thx. This small peptide can fit into a cavity between multiple RNA  
20 elements in the top of the head and its positive charge stabilizes the organization of these elements.

Proteins are often found bound to junctions between helices. S4 binds to the 5-way junction between H3, H4, H16, H17, H18 in the fpd, while S7 binds tightly to the junction of H29, H30, H41, H42  
25 in the tpd. Both proteins are important in early stages of 30S assembly of the body and head respectively.

The high resolution structure of the present invention agrees both with our previous model of the central domain, and subsequent high resolution structures that describe parts of  
30 this domain. New information on the protein subunits is also provided by the present invention as set out below, and this may be used by of skill in the art for the various applications of the present invention described herein.

### S18

35 S18 in the 30S consists of residues 19-88. It consists of two helices, and a third helical element formed by two short turns

from different parts of the structure that stack end-to-end. These helices together form a hydrophobic core. The C-terminus interacts with S11. Although similar in fold, the structure differs in detail from the one recently reported as part of the S6/S15/S18 complex with a fragment of RNA (Ref 31), which consisted of residues 35-84. Residues 63-80 of both structures are in agreement. Of those regions where the backbone trace is in a similar spatial location, our residues 25-40 align with their 37-52, 50-54 with 54-58, 58-62 with 59-63. The loop from 43-51 in our structure has no counterpart in theirs and has been bridged across by the peptide backbone. The C-terminus in their structure corresponds to part of this loop in ours. The differences probably arise from different interpretations of the electron density rather than conformational changes. These differences necessitate a reevaluation of some of the interactions of S18 with its neighbors, although most of the interactions previously described (Ref 31) involved the C-terminal helix, which is the same in both structures.

#### S11

S11 is a new structure and consists of two helices packed against a sheet, a type of fold seen in many ribosomal proteins. The sheet packs against the minor groove of the 690 loop (H23), and has a C-terminal extension that interacts with the C-terminal extension of S18 and also with the 790 loop (H24). Thus S11 stabilizes folding of the platform, by binding to both H23 and H24 near the tip of the platform.

#### S8

As observed previously (Ref 12) and in agreement with biochemical data, S8 binds near the H20/H21/H22 three-way junction and makes extensive interactions with H21 and H25. We now have molecular details of these interactions. In particular, two loops from S8 (87-92 and 112-118) wrap around the bulged bases 641-642 which were known to be required for high affinity binding of S8 32,33. The N-terminus of the protein also packs against the minor groove of the 825 stem (H25), thus helping the folding of the central domain. Residues K55 on S8 and 653 on RNA are next to each other as would be expected from crosslinking 29. The extension in Thermus S8 of the loop 69-76

packs against S2 from a symmetry related molecule.

The 5' domain binding proteins S17, S16 and S20

5 S17: Although originally thought to be exclusively a 5' domain binding protein, S17 also binds near the H20/H21/H22 three-way junction as we previously proposed in our low resolution structure (Ref 12) and consistent with crosslinking data (Ref 28). However, at that resolution, its orientation was ambiguous.

10 The core of S17 is known from NMR to be a  $\beta$  barrel with an OB fold, with long extended loops (Ref 34). These loops are disordered in solution but bind RNA in the 30S. In Thermus, there is a long C-terminal extension to S17 that is organized as an RNA-binding helix. The core of the protein and the C-terminal helix make extensive contacts with H11 and also contact H7. The  
15 C-terminal helix also contacts H21 in the central domain. Two long loops, loop 1 (26-36) and loop 2 (60-71) are ordered and interact with disparate domains of RNA exactly as predicted. Loop 1, which contains the site of neamine resistance, is inserted between H21 and a highly irregular structure at the  
20 base of H11. The very tip of loop 1 also touches the 560 loop of 16S RNA. Loop 2, which contains the site of a mutant defective in assembly, is involved in stitching together H7 and H11. Thus S17 interacts with H7, H11 and the 560 loop in the 5' domain, and H21 in the central domain.

25 S16: For a small protein, S16 has an extensive footprint throughout the 5' domain. Recently, the NMR structure of the protein along with its placement in the 5.5 Å map of the 30S has been described (Ref 35). Our structure reveals details of the RNA environment around the protein. All of the residues (1-88)  
30 are visible in the electron density, and were rebuilt using the NMR structure as a guide. The protein consists of an N-terminal sheet with two extended loops, and two short helices in the C-terminal end as previously described (Ref 35). All of the extensive contacts with 16S RNA are now clear. The  $\beta$  sheet is  
35 packed between the 608/620 internal loop of H21 on one side and a minor groove of H4 on the other. The two loops that extend out from this sheet both interact with RNA. Loop 1 interacts

with phosphates in major groove of H4, while residues 39-43 in loop 2 make contact with the phosphate backbone around the internal loop near 453 in H17. The first helix (53-61) also extends across the major groove of this internal loop, while the C-terminal end of the second helix along with the turn leading out of it point into a minor groove of H17. There is also interaction with the 110 loop of the 5' domain. Finally, the extended C-terminus lies across the minor groove at the tip of H17.

10 S20: In our low resolution structure (Ref 12), this protein was putatively identified as a three helix bundle in the 5' domain based on biochemical data that placed it at the bottom of the subunit (Refs 36,37). The current high resolution structure confirms this. The long N-terminal helix contacts the base of H6 and the tip of helix 44, and many conserved basic residues make salt-bridges with phosphates. Helices 2 and 3 of S20 interact with the minor groove of H9, and helix 3 also interacts with tip of H11 (263). Finally the extreme C-terminus of the protein is extended and lies along the minor groove of H9, which is longer in Thermus by 11 nucleotides. Thus S20 brings together several helices near the bottom of the subunit.

#### Proteins near the functional center

25 S4, S5 and S12 are clustered near the "functional center" of the ribosome and contain the sites of several important mutations.

In the structure of isolated S4 (Refs 38,39) the N-terminal domain was cleaved off prior to crystallization. This N-terminal region is organized as a tightly folded domain with a metal ion (presumably zinc) that is coordinated by four cysteines. The domain is packed against the body of the protein. While the N-terminus of S4 is highly conserved, the cysteines themselves are not. It is therefore likely that the addition of a "zinc finger" is for additional stability rather than essential for the fold. The linker residues 46-52 connect the N-terminal domain with the rest of the protein. All domains of S4 make intimate contacts with RNA. In particular, S4 makes extensive contacts with a five-way junction where H3, H4, H16, H17 and H18

come together in the 5' domain.

The N-terminal domain is packed against the 420 stem-loop (H16). The largely helical domain I is packed against a complicated region of RNA where H3 and the 507 bulge at the base of H18  
5 come together. The remaining domain of S4 makes extensive contact with the minor groove of the base of H16. In addition, it also makes contact with the tip of the H21, which is itself packed against H4. This position is consistent with the large body of biochemical data on S4 binding to 16S RNA.

10 As we previously noted (Ref 12), the C-terminus of S4 makes an extensive interface with S5. Most of the known mutations of S4 and S5 that confer the ram phenotype are located in this region (Refs 40,41). The interface consists of several highly conserved salt bridges, and some of the mutations break one or more of  
15 these interactions.

The structure of S5 is similar to the crystal structure of the isolated protein (Ref 42) with two important differences: The loop from residues 14-28 is folded back onto the body of the protein in the isolated structure, but is a fully extended  
20  $\beta$ -hairpin in the 30S. Also, the C-terminus of S5, which is disordered in the isolated structure, is mainly helical and packs against a complicated surface of S8 formed by many different strands.

S5 interacts closely with a region of the ribosome where the  
25 head and the body come together. In the head, the extended H35/H36 helix packs against H28, which forms the neck of the 30S connecting the body with the head. The tip of H36 makes contact with H26a, H2 and the central pseudoknot in the body. Protein S5 has contacts throughout this region, thereby  
30 stabilizing the conformation of the head with respect to the body.

The C-terminal sheet of S5 makes extensive interactions with the major groove of the H1 and the central pseudoknot. The N-terminal domain binds to the major groove of H36, as does the  
35 base of the  $\beta$ -hairpin. The tip of the hairpin interacts with the

phosphate backbone in H28 and is also very close to H34. Nucleotide 560 is very close to K121 in agreement with crosslinking data.

5 Most of the extensive interactions with RNA occur via major grooves or phosphate backbone. This explains the lack of a hydroxyl-radical footprint from S5 (Ref 27).

#### Protein S12

10 S12 is unusual both for its structure and location. It is unique among the 30S proteins in being on the interface side of the subunit. Its central core consists of  $\beta$ -barrel with an OB fold, a feature found in other proteins such as S17. This core binds together H18, the 530 stem loop (at the tip of H18), H3 and a part of H44 close to the decoding site. An unusual feature is a long extension that connects this core with a short helix  
15 at the N-terminus of the protein. This extension threads between the 560 loop and H12 on one side, and H11 on the other, to make contact with both S8 and S17 on the other side of the 30S.

20 S12 is also the only protein in the vicinity of the decoding site near 1492-1493 of RNA. It is the site of a number of functionally interesting mutations.

#### The head proteins

25 S7: Protein S7, whose structure in isolation was previously known, is known to be crucial for the assembly of the head (Ref 43). In the 30S, the entire sequence is visible, including the very basic N-terminus. S7 binds to a small but complex region of the tpd that encompasses two multiple-stem junctions at a corner of the head. The majority of the interaction surface consists of H29 tightly docked to the S-turn at the base of H43. This docking requires a tight turn at 1346, probably stabilized  
30 by S7 binding. Because S7 also makes interactions with H28, its primary surface of interaction encompasses all three of the helices around the H28/H29/H43 three-way junction. The very tight docking of H29 to H43 gives rise to a small region of very high negative charge density, which is bound by a surface of S7  
35 with very high concentration of positive charge (mainly S7 helices 1 and 4).

The second important interaction surface is centred on the second multiple stem junction that S7 binds, the H29/H30/H41/H42 junction. In this junction, H30 and the base of H42 are tightly packed together, with a tight turn between them. An S-turn  
5 between helices 41 and 42 mediates packing of H41 and H42, which also have a tight turn between them. H41 also packs very tightly against H43. S7 makes contacts to the phosphate backbone of H41, stabilizing its packing with H43, and to residues around 1240 and 1298 where the tight bends occur in the H29/H30/H41/H42  
10 junction. Contacts with U1240 are particularly intimate: the universally conserved bulge U1240 is deeply buried into a conserved hydrophobic pocket between the 35 and 115 loops of S7.

The  $\beta$ -hairpin is not tightly associated with 16S RNA, but probably fits tightly into the minor groove of the E-site tRNA.  
15 The structure is in rough agreement with a model of S7 binding to ribosomal RNA 44, but there are also significant differences, including the location of H43.

S9: S9 consists of a compact RNA-binding domain consisting of 2 helices packed against a 5-stranded sheet, with a third short  
20 helix at the C-terminal end of the domain. From this domain, there is a long 25 residue C-terminal tail that snakes into elements of the head RNA. S9 also interacts with S7 via a small hydrophobic patch.

The sheet of S9 makes extensive interactions with H38 and H39.  
25 It also has two loops that interact with the 1250 internal loop of H41. The short C-terminal helix interacts with 1177-1180 in H40.

The long C-terminal extension snakes between the H29-H43 junction on one side and the H38-H34 junction on the other to  
30 touch a portion of H31.

#### The S3 S10 S14 cluster

These three proteins form a cluster on the rear left-hand of the head, as the protein portion of the beak. S3 is clearly stacked on top of the other two proteins, consistent with the order of  
35 assembly.

S14 is bound in a crevice in the RNA and is mostly covered by S3 and S10. Almost the whole molecule contacts RNA, including helices H31, H32, H34, H38, and H43. A cross linked residue is in close proximity to the RNA (Ref 28).

- 5 S14 contains a zinc ion (Ref 45) coordinated by four cysteines from a CXXC-X12-CXXC motif. This motif is structurally similar to that found in the first zinc finger in the glucocorticoid receptor. This zinc binding motif is not conserved among all bacteria, although many of the residues surrounding it are,  
10 suggesting perhaps that in other organisms the protein folds via a hydrophobic core.

- S10 is structurally very similar to the S6 fold, with two helices packed against a 4-stranded sheet. Two of the strands in this sheet are connected by a long b-hairpin that extends out  
15 from the sheet and is inserted right into the center of the head RNA fold. The  $\beta$ -hairpin makes most of the contacts with RNA, including helices H31, H34 and H41. The two strands of the sheet pack into the shallow minor groove of H39, making contacts with backbone residues on both sides of the groove.

- 20 S3 contains two domains, both consisting of two helices packed against a 4-stranded sheet, which is similar to several other ribosomal proteins. In addition to the domains there is an N-terminal tail (all of which is visible). The C-terminal 30 residues are poorly conserved and disordered in the structure.

- 25 RNA contact is made by the N terminal tail and the C terminal domain. The N-terminal tail fits into a major groove of H34. The sheet in the C terminal domain also packs against H34.

- The N terminal domain makes few if any contacts with the RNA, but is mainly involved with making protein contacts with S10 and  
30 S14. A KH domain was predicted to occur in S3 (Ref 46). While elements of the KH domain are present in S3, they are split between the N- and C-terminal domains of the protein, so no KH domain as such is present.

Interestingly, the structure does not agree very well with

biochemical data. Although the protein does interact with H34, which it footprints (Ref 27), it is some distance ( $>10$  Å) from the H36-H37 region where it also has a footprint. Moreover, residues that crosslink RNA with iminithiolane (Ref 28) are on the same side of the N-terminal domain but about 10 Å from the nearest RNA. This RNA is the H33/H33a region, which is one of the most poorly ordered parts of our structure (as judged by the B-factor and weak density), suggesting that it could move in towards the N-terminal domain in other conformations.

10 S13 and S19

S13 and S19 form a loose dimer at the very "top" of the interface side of the head, extending both above and closer to the 50S than any of the head RNA. In spite of their location in this flexible region, they are both relatively well-defined in the electron density. Except for the C-terminal tail of S13, which reaches into the head and almost touches the tail of S9, none of these proteins are in contact with any other of the proteins in the small subunit. Together with S12, S11 and S15, these are among the few proteins that surround the region of intersubunit contact.

All 125 residues of S13 are visible in the structure. The N-terminus (app. 60 residues) forms a compact domain consisting of three small helices. Of this domain, only a small loop is in contact with the RNA and the domain appears to be clinging to the subunit only by virtue of its highly extended C-terminal region. This region begins with a long, straight alpha-helix that creeps along the top of the 30S head towards S19. It interacts mainly with the 1300 loop and H42. At this point the polypeptide chain bends by about 90 degrees, and the rest of the protein is mostly lacking in any secondary structure. This extended region curves around H41 into the head where it is buried in the RNA about 50-60 Å from the the globular, N-terminal domain. It contacts H30 in the head.

S19 consists of 92 residues. An NMR structure of isolated S19 showed a single globular domain consisting of a helix packed against a three-stranded sheet, in which residues 9-78 were ordered. In the 30S structure, residues 2-81 are visible in the

electron density. The C-terminus of the protein points towards the interface side and may become ordered in the 70S complex. Like S13, most of the globular domain of S19 is well separated from the RNA, but here both the N- and C-terminal extensions to the globular domain, as well as the loops 68-73 and 34-39 make contacts with H42. The C-terminal extension, like S13, bends around the RNA, to contact H31 while the N-terminus reaches H42 some considerable distance away. Thus, S19 straddles a portion of the head of the 30S. The residues in S13 and S19 that were crosslinked 48 are adjacent to each other in the structure.

### S2

Thermus S2 consists of 256 residues of which 7-235 are visible in our structure. The protein consists of a large central domain of about 200 residues that consists of a 5-stranded parallel sheet and four helices connecting them. Two helices that form a small coiled-coil motif protrude out of this domain. The protein is located on the back of the 30S at the interface between the head and the rest of the particle. While it is primarily regarded as a "head" protein, it also makes contacts with the central domain in our structure.

S2 is quite tenuously attached to RNA, which is consistent both with the fact that it is easy to wash off with salt and also that it is one of the last proteins to assemble onto the 30S (Ref 49). It binds RNA in H35-H38 in the head. There are also a few weak interactions with H25 and S8 in the central domain. It is not near H34 in our conformation of the 30S.

### Thx

This small 26 residue peptide was isolated and characterized from Thermus ribosomes (Ref 21). Thx fills a cavity formed by a number of different elements at the very top of the head. Residues 1-24 are visible in the electron density, of which 8-14 form a short helix, flanked by extended ends. It is surrounded by H42, the tip of H41, and the base of H41, while the bottom of the cavity is formed by the major groove of H43. The protein is highly basic, and there are extensive salt-bridges between these residues and phosphates of nearby RNA. Thus Thx stabilizes a number of different RNA elements that come close together near

the top of the head. Thx is known to exist in two other species of *Thermus* (Ref 21), and chloroplast ribosomes contain a nuclear-encoded Thx homologue (Ref 50). Because of its small size, it is difficult to determine whether it has counterparts in other bacterial genomes, but it would be surprising if homologues of the protein did not exist in many other bacteria.

## Example 2

This Example describes in more detail some functional insights provided by the high resolution analysis of the 30S ribosome. The example further describes the crystal structure of the 30S subunit complexed simultaneously with the antibiotics paromomycin, streptomycin and spectinomycin, which interfere with decoding and translocation. This work reveals the structural basis for the action of these antibiotics, and also suggests a model for the role of the universally conserved 16S RNA residues A1492 and A1493 in the decoding process.

The ribosome is a large, template-directed enzyme with sophisticated proofreading capabilities, with tRNA and mRNA as its ligands. There are three tRNA binding sites, designated A (aminoacyl), P (peptidyl) and E (exit), after their respective tRNA substrates (reviewed in ref. 1). The anticodon stem-loops (ASL) of the A- and P-site tRNAs bind to the 30S where they are base-paired to adjacent codons on mRNA. The E-site tRNA is bound in a similar orientation but whether the E-site tRNA is base-paired to the E-site mRNA codon or not is a matter of controversy (Refs 2,3).

The decoding of mRNA into protein requires the correct recognition of each A-site codon by the anticodon of the corresponding aminoacyl-tRNA (aa-tRNA). The difference in binding energy between the codon and anticodon with correct (cognate) versus incorrect (noncognate) tRNAs is too small to account for the high accuracy of translation (Ref 4). Initially, a ternary complex of elongation factor Tu (EF-Tu), aminoacyl tRNA and GTP binds to the A-site. The high level of accuracy of translation by the ribosome is thought to be a combination of the initial codon-anticodon interaction and a proofreading step occurring after GTP hydrolysis and release of EF-Tu (Refs 5,6). The proofreading step is considered to be especially important for discriminating cognate codon-anticodon interactions from energetically similar near-cognate ones. The mechanism by which proof-reading occurs remains unclear, although a number of models have been proposed (Refs 7,8). There are also models for decoding that do not invoke a separate proofreading step (Ref 9).

It has been suggested that the 30S switches between at least two distinct states during translation, and that stabilizing one state over the other can affect accuracy (Refs 10,11). One genetically well-characterized conformational switch in the 30S subunit is the helix 27 accuracy switch (Ref 11). Genetic and biochemical data support a model in which this switch may be part of a larger-scale conformational change that occurs between initial selection and proofreading of the A-site tRNA, or it may play a role in translocation.

Until recently, there has been a large disparity between the high resolution of the genetic and biochemical data that define the RNA components of the active sites of the 30S subunit, and the relatively low-resolution of the three-dimensional structures of ribosomes available. Here we analyse the high resolution structure of the 30S from *Thermus thermophilus* reported in the Example 1, and identify the molecular details of the interaction of mRNA and tRNA with the A, P and E sites of the 30S. We also are able to see the detailed environment around the helix 27 switch, and thereby suggest the kinds of conformational changes that are involved at the molecular level. As described in the accompanying paper, we use the standard H1-H45 nomenclature to describe the helical elements in 16S RNA.

Both subunits are major targets for antibiotics. By interfering with various aspects of their function, these antibiotics help to shed light on the mechanisms involved in translation. Although antibiotics were characterized several decades ago, molecular details of their mechanism were unclear in the absence of a high resolution structure.

We describe here the crystal structure to 3 Å resolution of 30S from *Thermus thermophilus* simultaneously complexed with streptomycin and paromomycin (which reduce translational accuracy), and spectinomycin (which interferes with translocation). Difference Fourier maps calculated after the refinement of our atomic model of the 30S against these data directly reveal the bound antibiotic molecules *in situ*. The structure allows us to rationalize much of the biochemical and genetic data on these antibiotics and propose models for their mode of action. In addition, the effect of paromomycin on the universally conserved bases A1492 and A1493 suggests a model for how they participate in the decoding process.

### Results

A single round of refinement against the native 30S coordinates resulted in a model with R/R<sub>free</sub> of 0.231/0.266. During refinement, the 30S structure changed significantly only in the vicinity of the paromomycin binding site. Elsewhere, the phosphate rmsd between the antibiotic-bound and free 30S

structures fluctuated about 0.45 Å, which is comparable to the coordinate error in the original model. Electron density for the antibiotics was visible in both difference Fourier maps and sigmaa-weighted  $2mF_o - DF_c$  maps. At 3 Å resolution, it was  
5 straightforward to position each antibiotic in an unambiguous orientation in the density, so that precise conclusions could be made about the location and interactions of each antibiotic in the 30S subunit. A second round of refinement using a model that included the antibiotics reduced the R/Rfree to 0.224/0.258.  
10 Crystallographic statistics are shown in Table 9 below.

In the discussion that follows, elements of 16S RNA are described by the helix numbering of Brimacombe and coworkers (Ref 13). The numbering used is for the *E. coli* 16S RNA  
15 sequence, as described in Example 1.

#### Functional analysis of the 30S structure

Mimics of P-site tRNA and mRNA in the 30S structure

The most functionally important parts of the 30S subunit are its substrate-binding A-, P- and E-sites. In our 30S crystal  
20 structure described above, the P-site is occupied by the tip of the spur stem-loop (H6) from a symmetry-related 30S subunit, and appears to mimic the P-site tRNA anticodon stem-loop (ASL). Henceforth the term 'spur' will refer to this symmetry-related stem-loop docked in the P-site. A superposition onto our 30S  
25 structure of the 7.8 Å 70S structure with mRNA and tRNA (Ref 14) using the common elements H27 and H44 resulted in a phosphate rmsd of only 2.3 Å after rejection of outliers. This superposition results in residues 27-47 of P-site tRNA almost exactly coinciding with residues 75-95 of the spur, suggesting  
30 that it is a good mimic of the ASL. Our 30S maps also contain electron density for single-stranded RNA that mimics mRNA codons in the P and E sites, with base pairing between the P-site codon and residues that correspond to the anticodon of the spur. The mRNA mimic is of uncertain origin, but its location and sequence  
35 (UCU, as inferred from the non Watson-Crick base-pairing geometries with the UUU of the spur) suggest that it corresponds to the 3' end of 16S RNA. The last nucleotide of our 16S model is A1534, which implies that four disordered nucleotides 1535-1538 would span the 7 Å distance to the first nucleotide of the

E-site codon mimic. Alternatively, it is possible that the 3' end of 16S RNA has been cleaved somewhere between A1534 and U1539 prior to or during crystallization.

#### Definition and descriptions of the 30S A-, P- and E-sites

5 The 16S RNA-based superposition of the 70S tRNAs and mRNA onto the 30S structure also provides a basis for defining the extent of the A-, P- and E-sites on the 30S subunit. There are no serious clashes between the A-, P- and E-site tRNAs and the 30S subunit. The most striking characteristic of the three binding  
10 sites is that they are all composed of RNA elements from at least two different domains. It is clear that independent motion of the head (tpd) or platform (cd), as has been observed in low-resolution cryo-EM studies (Refs 15,16), would have important consequences for movement of the tRNA-mRNA complex, as must  
15 occur during translocation.

#### The P-site

The spur contacts several discrete regions of 16S RNA, and surprisingly, two proteins. Most of the interaction surface is found on the minor groove of the spur stem and RNA nucleotides  
20 1338-1341, 1229-1230 and small portions of the C-terminal tails of proteins S13 and S9. There are seven hydrogen bonds from the minor groove of spur residues C91-C92 and G78 to the minor groove surface of G1338-A1339. Only one of these hydrogen bonds appears to be sequence-specific. A contact from K126 of S9  
25 appears to help stabilize this minor-groove to minor-groove packing interaction. Both 1338 and 1339 have previously been implicated in P-site binding (Ref 17). A second area of contact, nearly continuous with the first, is the interaction between the 16S 1229-1230 sugar-phosphate backbone and spur residues G77 and  
30 G78. This region of contact is extended by the C-terminal tail of S13. The other areas of contact are less extensive. One interaction is the stacking of U82 on C1400, which rationalizes the ASL 34-C1400 UV-induced crosslink (Ref 18). The other region is a packing interaction between A790 and spur residues 88-89,  
35 with a single hydrogen bond present. Finally, if the spur anticodon - mRNA codon helix were a few Ångströms wider, as it would be for a Watson-Crick-paired helix, it would make van der Waals contact with the base of G966, which has been implicated

as part of the P-site by chemical modification and binding experiments (Refs 17,19).

5 The P-site codon threads through the major groove of the upper portion of helix 44, in a universally conserved region of 16S RNA. There is a tight turn between nucleotides -1 and +1, between the last E-site and the first P-site codon nucleotides. This turn is stabilized by a hydrogen bond to the N1/N2 groups of the conserved residue G926, a residue previously implicated in P-site binding (Ref 19). Additional hydrogen bonds are  
10 observed between the 2' OH of +1 to the phosphate of C1498, and between the phosphate of +2 and the 2' OH of C1498. The phosphate of +2 also stacks on the base of C1498. The phosphate of +3 is within hydrogen-bonding distance of two conserved cytidine N4 groups, from C1402 and C1403. The +3 base also  
15 stacks on the sugar of C1400. Finally, it appears likely that there are several  $Mg^{2+}$  ions that may help stabilize the location of the P-site codon in the major groove of H44. One such ion appears to interact with the N7 atom of G1401, in agreement with biochemical data implicating this residue in P-site function  
20 (Refs 17,19). The contacts are also consistent with mRNA crosslinking data (summarized in 20).

#### The A-site

The A-site is much wider and shallower than the P- or E-sites, consistent with its much lower affinity for tRNA. The  
25 shallowness of the A-site may also reflect the need to allow rotation of the A-site codon-anticodon helix during or after GTP hydrolysis by EF-Tu. The RNA components of the A-site include portions of the 530 loop, H34 in the head, as well as residues 1492-1493 from the 3' minor domain, all of which have been  
30 previously implicated as elements of the decoding site (see articles in ref. 21). Interestingly, the electron density for A1492 and A1493 is not consistent with a single conformation for these residues in the absence of antibiotics. The only protein that appears even remotely likely to participate directly in  
35 decoding is S12, whose K47 loop is close to the A-site codon-anticodon helix. Other proteins are more distant: a poorly conserved part of the C-terminal tail of S13 lies between the A and P sites, and the conserved but disordered C-terminal 12

residues of S19 may be in approximately the right location to interact with the upper portion of the A-site ASL.

#### The E-site

Unlike the A- and P-sites, the E-site consists mostly of  
5 protein. Proteins S7 and S11 have a small interface that binds  
the minor groove of the E-site ASL. The position of the highly  
conserved beta-hairpin of S7 suggests that it might help  
dissociate the E-site codon- anticodon. The RNA portion of the  
E-site makes relatively few interactions with the E-site ASL, in  
10 accordance with the observed failure of the E-site tRNA to  
footprint 16S RNA (Ref 17). The minor-groove surface of the  
conserved 16S residues 693 and 694 may interact with the minor-  
groove surface of the 37-39 residues of the E-site ASL.

#### The Helix 27 accuracy switch

15 In addition to the ligand-binding A-, P- and E- sites, the 30S  
subunit must also contain functionally important conformational  
switches. Only one of these, involving H27, has been well  
characterized genetically and biochemically (Ref 11). H27 has  
been proposed to have two alternative base-pairing schemes  
20 during translation, a ribosomal ambiguity (*ram*) or error-prone  
form with nucleotides 885-887 paired to 910-912, and an  
alternative hyperaccurate or 'restrictive' form with 888-890  
paired to 910-912. The *ram* form features an S-turn motif in H27,  
which is present in our structure. It packs against the minor  
25 groove of H44, just below the decoding site. Switching to the  
restrictive form must disrupt the S-turn and change the packing  
of H27 and H44, and perhaps the structure of the decoding site.  
Indeed, strains containing S12 restrictive mutations exhibit  
altered chemical reactivity of RNA residues at the H27-H44  
30 interface (Ref 10). However, H27 also packs against several  
other helices: the conserved hairpin loop at the end of H27  
packs against the platform (H24), and there is a long-range  
base-pair between H27 and the root of H11. Thus it seems  
probable that the switch also affects other helix-helix  
35 interactions, and in fact there could be a network of coupled  
switches amongst H1, H27, H18, H34, and H44. In support of this  
possibility, chemical protection experiments suggest that a  
number of RNA residues in these helices have greater chemical

reactivity in the 'restrictive' state, which suggests that the restrictive state may be a more 'open' state of the 30S subunit (Ref 11).

Ram mutations often occur in S4 or S5 (reviewed in ref. 22), all but one of which map to the interface between the two proteins. S4 ram strains exhibit increased chemical reactivity in two RNA sites at the interface between the central pseudoknot (H1) and the 530 pseudoknot (H18). Several streptomycin resistance mutations are also found at this RNA-RNA interface.

Interestingly, the S4-S5 and the H1-H18 interaction surfaces are contiguous, which suggests that this hybrid RNA-protein surface may move, and that an important function of the S4-S5 interaction may be to modulate the interaction of H1 with H18. It is likely that ram mutations preferentially destabilize the restrictive state, as with the S4/S5 interface and its RNA extension, or in other cases, stabilize the ram state.

#### Interaction of antibiotics with the 30S Spectinomycin

Spectinomycin inhibits EF-G catalyzed translocation of the peptidyl-tRNA from the A site to the P site (Ref 23). The fused ring system in spectinomycin makes it a rigid molecule. It binds in the minor groove at one end of H34, makes a single contact with a backbone phosphate and makes hydrogen bonds to a number of bases (Fig. 7). The most interactions are made with G1064 and C1192, consistent with protection studies 24 and mutagenesis data on spectinomycin resistance (Ref 25). These two bases are held too far apart to form Watson-Crick base pairs, but are able to make a single hydrogen bond. A loop of S5 and part of H28 of 16S RNA are within 5 Å of the spectinomycin binding site, but in this state do not make direct contacts with it. It is possible, however, that in other conformations of the 30S, spectinomycin is in more direct contact with these regions.

Translocation of tRNA from one site to the next must necessarily involve movement of elements of the head. It is probable that such movements would involve H34 and a possible rearrangement of the connections between it and helices H35 and H38. The structure suggests that the rigid spectinomycin molecule binds

near this pivot point of the head and sterically blocks movement although it is also possible that it acts to stabilize the upper stem of H34 (Ref 25). As mentioned above, mutations in S5 that cause resistance to spectinomycin (Ref 26) do not make direct  
5 contacts with the antibiotic. Rather, they map to a loop that stabilizes the interaction between H1 and the H35-H36 region which is directly connected to H34. An attractive hypothesis is that the mutants destabilize this interaction, and by thus removing the network of interactions that stabilizes the  
10 conformation of the head to the body via S5, allows it to move even when spectinomycin is bound.

### Streptomycin

Early experiments suggested that streptomycin made ribosomes error prone by predominantly affecting the proofreading step  
15 (Ref 27). More recent data suggest interference of both the initial selection and proofreading (Refs 28-30).

Streptomycin is tightly bound to the phosphate backbone of 16S RNA from four different parts of the molecule via both salt bridges and hydrogen bonds (Fig. 8). It also makes contact with  
20 K45 from protein S12. The four regions of 16S RNA (1490, 915, 526, and 13) have all been implicated in streptomycin binding on the basis of protection (Ref 24), crosslinking (Ref 31) and mutagenesis data (Refs 32-34).

The tight interactions observed for streptomycin suggests that  
25 it preferentially stabilizes the *ram* state seen in the crystal structure. The restrictive A-site has a low tRNA affinity, while the *ram* state has a higher affinity (Refs 7,11). Therefore, by stabilizing the *ram* state, streptomycin would be expected to increase initial binding of non-cognate tRNAs. The preferential  
30 stabilization of the *ram* state would also make the transition to the restrictive state more difficult, thereby also affecting proofreading. Thus our results offer a structural rationale for the observed properties of streptomycin.

This stabilization of the *ram* state by streptomycin suggested by  
35 our structure can also explain much of the genetic data on the antibiotic. Mutations in S12 lead to a hyper-accurate phenotype

(reviewed by 22). A weak phenotype manifests itself as streptomycin resistance, whereas a strong phenotype (often the result of multiple mutations) leads to streptomycin dependence. Most of these mutants are to varying degrees more hyperaccurate and slower than wild type ribosomes, consistent with destabilization of the *ram* state with respect to the restrictive state.

All the mutations in S12 map to protein loops that connect and hold in place the 908-915 and 524-527 regions, with the exception of one mutant K56 (E.coli K53) which contacts H44. Thus S12 stabilizes the same region that is stabilized by streptomycin. In the resistance mutations, the *ram* state is destabilized sufficiently so that the additional stabilization induced by streptomycin does not trap the ribosome in this state. In the streptomycin dependent mutants, the *ram* state is so destabilized that the restrictive (hyperaccurate) form predominates. Streptomycin can then help stabilize the *ram* state sufficiently to restore the balance between the two states and help restore translation.

This hypothesis is supported by analysis of the K45R (E.coli K42) mutant, which is the only known mutant that is resistant to streptomycin but not hyperaccurate (Ref 22). K45 forms a salt bridge with phosphate A913 and thus contributes to stabilization of the *ram* state. It also makes direct hydrogen bonding contacts to two OH groups on streptomycin. Mutation of this lysine to arginine would disrupt the hydrogen bonding and thereby reduce the affinity of the 30S for streptomycin, leading to resistance. However, the mutation would leave the salt bridge intact, so that the *ram* form is not destabilized and thus translation remains normal.

A number of mutations in rRNA also lead to hyperaccuracy (Refs 32,33,35-38). Some of these nucleotides are involved in hydrogen bonding interactions in regions close to the streptomycin binding site. Thus the mutations disrupt interactions that help to stabilize the *ram* state. Others such as A915 make no contacts with any other bases. It is possible that mutation of this base leads to more favourable contacts in

the restrictive state, thus acting by stabilizing the restrictive state rather than destabilizing the *ram* state.

As discussed above, we suggest that *ram* mutations in S4 and S5 preferentially destabilize the restrictive state, thus shifting the balance towards the *ram* state. The observation that *ram* mutations increase the affinity of ribosomes for streptomycin (Ref 39) is consistent with this model. Our results provide a structural basis for the notion that a delicate balance exists between the *ram* and restrictive states for optimal translation, and also explains how disruption of this balance leads to the various phenotypes observed. A definitive test of this model must await an atomic resolution structure of the restrictive form.

#### **Paromomycin**

Paromomycin is a member of the aminoglycoside family of antibiotics, and increases the error rate of the ribosome. This family is thought to reduce the dissociation rate of A-site tRNA from the ribosome (Ref 28), but recent experiments also suggest that it increases the initial binding affinity of tRNA (Ref 7).

Paromomycin binds in the major groove of H44 (Fig. 9) in a location that is in agreement with mutagenesis and protection data (Refs 24,40). Ring IV contacts the backbone of both sides of H44, while ring III makes only weak contacts with the RNA. Ring II forms tight interactions with both bases and backbone of the RNA, while ring I inserts into the RNA helix and helps to completely flip out bases A1492 and A1493, which are not well ordered in the structure of the antibiotic-free 30S. Ring I mimics a nucleotide base, stacking against G1491 and hydrogen-bonding with A1408. In addition it forms a tight H-bond interaction with the phosphate backbone of A1493 which helps lock the flipped out bases in place. The structural basis for resistance mutations has been described previously with the NMR structure of a complex of paromomycin with an RNA fragment corresponding to its binding site (Ref 41), which is generally similar to our structure. The main differences are that ring IV is dynamically disordered in the NMR structure, and A1492 and A1493 are flipped out to a far greater extent in our structure.

Consequently we do not see the base pair between A1408 and A1493 that was observed in the NMR structure.

Rings I and II of paromomycin are found in a number of other antibiotics including gentamycin. An NMR structure of  
5 gentamycin bound to the same fragment of H44 showed that these two rings interact with RNA in the same way as in paromomycin (Ref 41). This suggests that other aminoglycosides that bind to the decoding centre on H44 induce errors in translation by the same mechanism as paromomycin.

10 With respect to the model of the A-site codon and tRNA ASL described above, the flipped out bases point directly into the A site and are positioned to interact with the minor groove of the codon-anticodon helix. In this modeling, there are rather  
15 strict steric constraints on the A-site anticodon and especially the codon, which is also covalently attached to both the P-site codon and downstream message. Thus, despite the uncertainties associated with modelling, it appears unlikely that the A1492-A1493 could interact with any portion of the codon-anticodon  
20 helix other than its minor groove. This model provides clues as to how paromomycin increases the affinity of the A site for tRNA. It seems likely that in the absence of paromomycin some energy is required to flip out A1492-A1493 so they can contact the tRNA, and presumably this energetic cost is compensated by  
25 the formation of favorable interactions with tRNA. By binding to H44, paromomycin forms a structure in which these bases are already flipped out, thus reducing the energetic cost of both cognate and non-cognate tRNA binding and increasing tRNA  
affinity for the A site.

#### **Implications for decoding in normal translation**

30 The universally conserved residues A1492 and A1493 are required for viability in *E. coli* (Ref 42, and are footprinted by the A-site codon and tRNA (Ref 17). Experimental evidence for hydrogen bonding between the N1 atoms of A1492 and A1493 and 2'  
OH groups on the message (Ref 42) as well as modelling efforts  
35 (Refs 42,43) have implicated these bases in the decoding process, but it has not been clear how hydrogen bonding to mRNA alone could discriminate sufficiently between cognate and non-

cognate tRNAs. Moreover, in the structure of the 70S with tRNA and mRNA (Ref 14), these bases were considered too distant from the codon-anticodon helix to play a direct role in decoding. A flipped-out conformation for 1492-1493 suggests a decoding model that can reconcile these conflicting views.

The crux of decoding is the discrimination of near-cognate from cognate tRNAs. In the 30S structure, with the A-site codon and anticodon modelled as described above, the flipped-out A1492 and A1493 lie in the minor groove of the codon-anticodon helix, and form a portion of the decoding surface. We propose that the 1492 and 1493 adenine bases hydrogen-bond simultaneously to 2' OH groups on both sides of the codon-anticodon helix, in a structural motif that is not uncommon elsewhere in the 30S structure. Two adenines can monitor a large portion of the minor groove of three consecutive base pairs. Since the distance between the 2' OH groups across the groove is a function of the base pairing geometry, the formation of simultaneous hydrogen-bonds to both strands of the codon-anticodon helix should be sensitive to distortions arising from mispairing. We propose that the remainder of the decoding surface is composed of conserved RNA residues from the 530 pseudoknot and/or H34, which are nearby, which may monitor the shape of the correct anticodon-codon helix and contribute additional bonds. Significantly, the adenine-rich motifs that recognize minor grooves elsewhere in the 30S structure often recruit other RNA residues to complete an interaction surface.

There are at least two possible ways that adenines can hydrogen-bond simultaneously to 2' OH groups on both strands of a regular helix. The docking may involve hydrogen bonding of either adenine N1, N6, and N3, or of adenine N1, N6, and N7. The former mode would result in a steric clash if the adenine were mutated to a G, while the latter would not. The distinction is important because experiments supporting a model in which A1492 and A1493 hydrogen-bond to the 2' OH of the codon made use of adenine to guanine mutants, which seem to rule out the N1-N6-N3 mode (Ref 42). Another argument favoring the N1-N6-N7 mode is that it allows formation of a sequence-independent hydrogen bond between the adenine N6 atom and the O2 or N3 hydrogen-bond acceptor in

the codon-anticodon helix (Ref 43). However, the relative orientations of our flipped-out A1492-A1493 residues and the A-site codon-anticodon duplex appears to be more consistent with the N1-N6-N3 mode. The third or wobble position of the codon-anticodon helix could be monitored less stringently by the A1492-A1493 in this scheme, thus allowing for the greater freedom for base-pairing at the wobble position. A conclusive test of the decoding model will require the determination of the structure of cognate tRNA and mRNA ligands bound to the A-site in the restrictive form of the ribosome.

### Conclusions

In the present invention, we have analysed the functional implications of the 30S structure reported in Example 1. This has allowed us to identify molecular details of the interactions made by A-, P- and E-site codons and tRNA with the 30S. We have also determined the structure of the 30S in complex with three antibiotics that target different regions of the 30S ribosomal subunit and work in different ways. The detailed knowledge of their binding sites from the structure of their complex with the 30S subunit should help to serve as the basis for the design of novel drugs that target bacterial protein synthesis. It is striking that all three antibiotics bind at the functional center (with streptomycin and paromomycin being particularly close to each other). Another common theme is that all three antibiotics work by altering a delicate balance between conformational states of the 30S as it goes through the process of translation. Each of them sheds light on a different but fundamental process during translation: Spectinomycin on translocation, streptomycin on the switch between the ram and restrictive states, and paromomycin on decoding. Finally, the structure suggests a direct role for A1492 and A1493 in the decoding process.

### Methods

Purification of ribosomal subunits, followed by crystallization, cryoprotection and flashcooling were carried out exactly as described in the Exmple 1, except that crystallization was carried out in the presence of a 10-fold molar excess of each of a mixture of streptomycin, paromomycin and spectinomycin. Also,

no cobalt hexammine was included in the cryoprotectant, and antibiotics were present throughout the transfers into cryoprotectant solutions.

5 Data were collected on beamline ID14-4 at the ESRF in Grenoble,  
and integrated and scaled using HKL-2000<sup>44</sup>. The refined 3 Å  
structure of the 30S with the cobalt ions removed was used as a  
starting model for refinement using CNS (Ref 45). Rigid body  
refinement was followed by positional refinement using energy  
10 minimization and finally by grouped B-factor refinement. For  
cross-validation, 5% of the reflections were left out of the  
refinement, and care was taken to ensure that these corresponded  
to the same 5% that were omitted for the refinement of the  
original 30S model.
